(54) Title: SET OF TOOLS FOR USE IN URETHROPEXY PROCEDURES

## (57) Abstract

An anchor-insertion tool for securing an anchor having a suture extending therefrom to a structure within a patient's body is provided. The anchor-insertion tool comprises an elongate shaft having distal and proximal ends, an anchor-receiving tip at the distal end, at least one groove extending from the tip at least partially along the length of the shaft, and at least one depression extending about the circumference of the shaft and intersecting the groove. A loaded anchor-insertion tool is provided, along with a surgical method for employing the anchor-insertion tool. A surgical template and suture retriever are also provided.

## SET OF TOOLS FOR USE IN URETHROPEXY PROCEDURES

### BACKGROUND OF THE INVENTION

#### 1. Field of the Invention

The present invention is directed towards a bone anchor-insertion tool, a suture retriever, a surgical template and a surgical method employing the same, all of which are particularly suited for a laparoscopic urethropexy procedure for the correction of female stress urinary incontinence. More particularly, the present invention provides apparatus and methods for performing the urethropexy through laparoscopic techniques, thereby greatly reducing the duration, discomfort, and recovery period of such surgeries.

#### 2. Description of Related Art

Female stress urinary incontinence (SUI), defined as the unintentional loss of urine, can be a socially unacceptable problem for many women. Most often, the incontinence occurs during coughing, sneezing, or physical activity in women afflicted with this problem. While effective surgical treatment for this condition has existed for nearly 50 years, the procedures typically involve major abdominal surgery with accompanying post-operative limitations lasting six to eight weeks. Because of the nature of these surgical procedures, many women simply resort to diaper-like incontinence pads, or simply avoid any activities which result in the unintentional loss of urine.

In the normal resting state, the external pressure exerted on the collapsible urethra by the surrounding musculature is greater than the pressure exerted on the bladder, and therefore continence is maintained. During moments of coughing, sneezing, or physical activities, greater pressure will be exerted on the dome of a filled bladder. In women not afflicted with stress incontinence, a corresponding increase in the external pressure on the urethra acts to prevent the unwanted loss of urine from the bladder. Sufferers of SUI, however, aren't so fortunate.

Stress incontinence is generally caused by two etiologies: a spastic detrusor muscle; or a loss of support of the periurethral tissue at the urethra-vesicular junction ("UVJ" - the region where the urethra enters the bladder). When the latter situation occurs, the UVJ will sag into the vagina, thereby reducing the pressure which can be exerted on the urethra during moments of stress. Diagnosis of any sagging of the UVJ can be easily determined by inserting the tip of a cotton swab into the urethra until it reaches the UVJ. The patient is then asked to bear down as if urinating, and loss of the UVJ support is readily identified by the upward movement of the wooden end of the cotton swab. In this test, the external urethral meatus acts as a fulcrum for the tip of the swab, and the elevation of the opposite end indicates the downward descent of the UVJ. U.S. Patent No. 4,072,144 provides an alternative device which may be utilized to readily measure the angle of the UVJ in a similar manner.

The first urethropexy procedure for eliminating SUI caused by a sagging urethra was developed in 1948 by Drs. Marshall, Marchetti, and Krantz, and generally involves the fixation of the periurethral tissue at the UVJ on either side of the urethra (MMK procedure). Fixation in the MMK procedure, also known as urethropexy or abdominal culposuspension, is accomplished by suturing the periurethral fascia at the UVJ on either side of the urethra to the periosteum of the pubic bone. The procedure essentially alters the angular relationship between the urethra and bladder by elevating the UVJ, and therefore preventing

the sagging of the UVJ when downward pressure is applied to the region by various stresses.

5 The MMK procedure has been perfected over the years, however the essential principles have remained the same. In 1955 Burch developed the technique of affixing the periurethral fascia bilaterally to Cooper's ligament, thereby resulting in a technically easier procedure because of the previous difficulties in passing a needle through the periosteum of the pubic bone. Although the Burch procedure has been performed laparoscopically, the five-year failure rate for the open Burch procedure is approximately 60%. A laparoscopic  
10 Burch procedure is even more problematic since it is extremely difficult and time-consuming to tie sutures laparoscopically.

Alternatively, urological procedures such as that of Stamey, Raz and Peyerra have been developed, however these are typically blind procedures which require the passing of long needles through the rectus fascia to the  
15 periurethral fascia utilizing a cystoscope. Although these urological procedures avoid the 10-centimeter midline or Pfannenstiel incision and its required three-day or longer hospital stay, the gynecological procedures of MMK, Burch and others have proven to be the most effective. In fact, the scarring of the urethra and interior bladder as well as the scarring of the periurethral tissues, aids in  
20 fixation of all of the involved tissues during the MMK and Burch procedures, thereby assisting in the prevention of incontinence.

Recently, a modified version of the MMK procedure has been developed which utilizes bone anchors secured directly to the pubic bone on either side of the symphysis for fixation of the UVJ. The apparatus for performing this modified  
25 MMK procedure are sold by Mitek Surgical Products, Inc. of Norwood, Massachusetts, and a number of U.S. patents concern these products (see, e.g., US Patent No's 5,207,679, 5,217,486 and 4,899,743). In the Mitek-MMK procedure, a Pfannenstiel incision must be made in the abdomen in order to provide access to the space of Retzius. The space of Retzius is in actuality a

"potential" space in that it contains various connective tissues and fats which must be dissected in order to provide sufficient access to this region. In fact, this connective tissue, particularly the areolar adventitial tissue, generally breaks down after delivery of a child, and this breaking down of the connective tissue often contributes to the onset of SUI in many women.

Once the space of Retzius has been dissected in the Mitek-MMK procedure, small anchors are secured in the pubic bone on either side of the pubic symphysis. Each of the bone anchors has a suture attached thereto, and these sutures are threaded through the periurethral tissue on either side of the urethra. The sutures are then tied off in the abdomen so that the periurethral tissue is pulled upward, which in turn restores the angle of the urethra at the UVJ, thereby restoring the urethra to its proper location. While the Mitek-MMK procedure is highly effective, it is a lengthy and complicated procedure which can generally only be performed by highly-skilled surgeons.

The present invention offers a unique anchor-insertion tool for securing an anchor within a patient. This apparatus is particularly suited for laparoscopic urethropexy, however, its use is not so limited. A suture retrieval tool and template for use in urethropexy procedures is also provided.

## BRIEF DESCRIPTION OF THE DRAWINGS

While the specification concludes with claims particularly pointing out and distinctly claiming the present invention, it is believed that the same will be better understood from the following description taken in conjunction with the accompanying drawings in which:

Figure 1 is a cross-sectional view taken through the midline of a patient who has lost support of the periurethral tissue at the UVJ, and is thereby suffering from stress urinary incontinence (SUI);

Figure 2 is the same view as Fig. 1, however the structural defect has been corrected using the methods and apparatus of the present invention;

Figure 3 is a top plan view of a bone anchor used in the method of the present invention;

### SUMMARY OF THE PREFERRED EMBODIMENTS

It is an object of the present invention to provide an improved anchor-insertion tool for use in a laparoscopic urethropexy procedure.

10 It is another object of the present invention to provide an improved anchor-insertion tool wherein suture tails extending from the anchor can be controlled during the insertion process in order to facilitate tying of the sutures.

It is yet another object of the present invention to provide a pre-loaded anchor-insertion tool.

15 It is still another object of the present invention to provide a surgical template and a suture retriever for use in a laparoscopic urethropexy procedure.

20 The forgoing object can be accomplished, in accordance with one aspect of the present invention, by providing an anchor-insertion tool for securing an anchor having a suture extending therefrom to a structure within a patient's body. The anchor-insertion tool comprises an elongate shaft having distal and proximal ends, an anchor-receiving tip at said distal end, at least one groove extending from said tip at least partially along the length of said shaft, and at least one depression extending about the circumference of said shaft and intersecting said groove. The anchor-insertion tool further preferably comprises at least one retaining band positioned in said depression, wherein a suture extending from an

anchor positioned on said tip may be slidably held within said groove by said retaining band. A handle may also be provided at the proximal end of said shaft.

5 The anchor-insertion tool may also have a second groove extending from the tip and at least partially along the length of the shaft, wherein the depression also intersects this second groove. The grooves may extend along opposite side of said shaft. A second depression preferably extends about the circumference of the shaft, wherein this second depression intersects both of said grooves. A second retaining band may be positioned within said second depression.

10 In order to ensure that elastic bands slidably hold the suture in place, the grooves should be deeper than the depressions. The retaining bands also preferably comprise elastic O-rings. A suture threader is optionally provided, and this threader comprises a wire having distal and proximal ends, and a loop at said distal end. The threader is positioned within the grooves and beneath said retaining bands such that a suture may be inserted into said loop and said  
15 threader may then be pulled away from said groove in order to thread the suture into the groove beneath said retaining band. The threader further has a handle at its proximal end, wherein said loop is positioned adjacent said tip, and wherein said threader may be pulled away from said groove by means of said handle. A pair of such suture threaders may be provided, each comprising a wire having  
20 distal and proximal ends, and each having a loop at their distal ends, one of said threaders positioned within each of said grooves and beneath said retaining bands such that a suture tail may be inserted into each of said loops and said threaders may then be pulled away from said groove in order to thread the suture tails into said grooves beneath said retaining bands. Both of the threaders may  
25 be secured to a single handle at their proximal ends.

A loaded anchor-insertion tool of the type described above is also provided, wherein an anchor having a suture extending therefrom is positioned on said anchor-receiving tip, said suture extending from said tip along the length of said shaft within said groove, and said retaining band positioned about said

shaft such that said suture is held between said band and said groove. The suture is preferably slidably held within said groove by said retaining band. The groove should be at least as deep as the diameter of said suture, in order to ensure that the suture is not exposed during the insertion process. The groove is preferably longer than the portion of said suture which extends along the length of said shaft, thereby further ensuring that no portion of the suture is exposed.

A surgical method for laparoscopically securing an anchor to the pubic bone of a patient during a laparoscopic urethropexy procedure is also provided. This surgical method comprises the steps of:

(a) providing a loaded anchor-insertion tool comprising, in combination:

- an anchor-insertion tool comprising an elongate shaft having distal and proximal ends, an anchor-receiving tip at said distal end, and at least one groove extending from said tip at least partially along the length of said shaft;
- an anchor having a suture extending therefrom; and
- at least one retaining band;

wherein said anchor is positioned on said anchor-receiving tip, said suture extends from said tip along the length of said shaft within said groove, and said retaining band is positioned about said shaft such that said suture is held between said band and said groove;

(b) inserting the distal end of said loaded tool through a cannula into the patient's body; and

(c) securing said anchor to the pubic bone of the patient.

The cannula preferably comprises the operative channel of a laparoscope. This surgical method may also comprise the step of laparoscopically creating a bore in the pubic bone, such that the anchor is secured to the pubic bone by urging the anchor into said bore. The insertion tool may further comprise a handle at its distal end, and the surgical method may thus further comprise the step of pulling said insertion tool away from said bore and said anchor which is secured

in said bore by means of said handle, such that said suture slides beneath said band thereby ensuring that said suture extends between said anchor and said insertion tool.

5 A surgical template for guiding at least one suture through the periurethral fascia and vaginal mucosa adjacent a patient's urethra during a urethropexy procedure is also provided. This template comprises:

- (a) first and second wing members extending laterally from opposite sides of the template;
- (b) at least one suture guide aperture positioned in each of said wing members at a predetermined location; and
- 10 (c) a groove extending along the under surface of each of said wing members and intersecting said apertures;

wherein said grooves act to guide the insertion of the tip of a suture retriever into said apertures when said template is positioned within the vagina of a patient.

15 The under surface of said wing members adjacent said apertures is preferably beveled in order to assist in manipulation of a suture retriever inserted through said apertures, and the upper surface of said wing members adjacent said apertures is likewise beveled.

20 A suture retrieval tool for use in a laparoscopic urethropexy procedure is also provided, this retrieval tool comprising:

- (a) a retrieving end comprising a shaft and a sharp tip capable of penetrating tissue, said shaft having a longitudinal axis, said tip preferably having a width less than the that of said shaft; and
- (b) a handle having a longitudinal axis;

25 whereby said retrieving end may be inserted into a vagina, through the vaginal mucosa and periurethral tissue adjacent a urethra, and into the space of Retzius, such that said retrieving end may be employed to snare a suture positioned in the space of Retzius for retrieving said suture into the vagina. The shaft should be round and the tip is substantially flat. The tip may further have a sharpened

30 distal end and a suture slot located proximally of said distal end, said slot having

and entrance thereto, and said slot capable of snaring a suture therein. The entrance to the slot is spaced inwardly from said shaft.

### DETAILED DESCRIPTION OF THE INVENTION

Referring now to the drawings in detail, wherein like numerals indicate identical elements throughout the views, Fig. 1 is a cross-sectional view taken along the midline of a patient suffering from stress urinary incontinence (SUI). For reference, Fig. 1 depicts bladder 1, urethra 2, urethra-vesicular junction (UVJ) 3, periurethral tissue 4, vagina 5, uterus 6, pubic symphysis 7, and space of Retzius 8. In this patient, urethra 2 and the associated periurethral tissue 4 have sagged into vagina 5. During periods of stress such as coughing or sneezing, pressure will be exerted on bladder 1. Due to the collapse of urethra 2, the surrounding musculature will be unable to provide sufficient counteractive pressure on urethra 2 to prevent loss of urine during these periods of stress. As known from the methods of the prior art, particularly the MMK procedure, fixation of periurethral tissue 4 at UVJ 3 on either side of urethra 2 will act to support the urethra and prevent the sagging of urethra 2 into vagina 5. This in turn will enable the surrounding musculature to provide sufficient pressure on urethra 2 to prevent loss of urine during moments of stress.

Figure 2 depicts the resulting support of urethra 2 at UVJ 3 by means of the surgical procedure of the present invention. It should first be noted that pubic bone 12 is shown in Figure 2, and is that portion of the pubic bone lying immediately to the right of the pubic symphysis. As will be more fully understood later, the anchors of the present invention are secured in the pubic bone on either side of the pubic symphysis. A bore 13 has been produced in pubic bone 12, and anchor 9 has been secured within bore 13. It should be noted that bore 13 and anchor 9 have been enlarged for purposes of clarity. A suture 10 is secured to anchor 9, and the two tails of suture 10 extend downwardly through the space of Retzius 8 into vagina 5. The tails of suture 10 extend into the vagina immediately to the right of urethra 2 through periurethral tissue 4 at UVJ

3. In the vagina, the two tails of suture 10 are tied to one another such that suture 10 provides an upward force on periurethral tissue 4 on the right side of urethra 2 adjacent UVJ 3. An identical anchor and suture combination is secured to the pubic bone on the left side of the pubic symphysis, and the suture enters  
5 the vagina in a similar fashion as before in order to provide an upper force on periurethral tissue 4 on the left side of urethra 2. In this fashion, the sutures on either side of the urethra act to restore the angle of the urethra at the UVJ.

As will be described in further detail below, the securing of the anchors to pubic bone 12 can be accomplished laparoscopically. Suture 10 may then be  
10 pulled into vagina 5 through periurethral tissue 4 immediately adjacent to urethra 2. The two tails of suture 10 may then be tied to one another within vagina 5 by hand. It has been found that the portion of suture 10 positioned within vagina 5 will be epithelialized within a few days after the procedure. In this fashion, suture 10 will not cause any discomfort or irritation to the patient since suture 10 will  
15 quickly be covered by the epithelium of vagina 5.

## SURGICAL TECHNIQUE

### A. Preparatory Procedures

Identification of patients suitable for the techniques of the present invention may be made by any of the known techniques for identifying patients  
20 amenable to SUI correction by MMK or similar procedures. For example, as discussed previously a cotton swab may be inserted into the urethra until the end of the swab reaches the UVJ. The patient is then asked to bear down and the movement of the portion of the swab outside of the urethra is monitored. The external urethral meatus will act as a fulcrum for the cotton swab, and a loss of  
25 urethral support at the UVJ can be readily identified by the upward movement of the external end of the cotton swab. This indicates a downward descent of the urethra at the UVJ, which in turn provides an indication of the structural cause

of the patient's SUI. Other means known in the art, however may be employed to confirm the diagnosis and/or to rule out other possible causes.

5 The preoperative preparation of the patient follows standard procedures for laparoscopic and gynecological surgeries, however no enema is needed. The patient is placed in the dorsal lithotomy position, and standard parenteral antibiotics are applied. Preferably, the patient is also placed under general anesthesia in order to minimize discomfort.

10 A Foley catheter (16 French with 10cc balloon) is then inserted into the urethra. The balloon of the Foley catheter is inflated, and the catheter is gently pulled outwardly to ensure proper placement of the balloon at the juncture of the bladder and the urethra. Proper placement of Foley catheter 14 is shown in Fig. 17 wherein a portion of vagina 5 has been cut-away for purposes of clarity. Bladder 1 is thereafter drained in the usual fashion using the catheter so that the bladder will become deflated. As will be understood below, maintaining the bladder in a deflated state greatly simplifies the procedure of the present invention. In addition, when the template of the present invention is employed, it is preferable that Foley catheter 14 be positioned in the manner shown in Fig. 17 for reasons which will be described further herein.

20 It is also desirable to measure the length of the patient's urethra in order to ensure proper placement of the supporting sutures, particularly when the template of the present invention is employed. If the sutures are placed too close to the bladder, there is a considerable risk that the suture retrieving tool will puncture the bladder. Likewise, if the sutures are placed too far from the UVJ, then proper support of the urethra will not be accomplished. The length of urethra 2 may be readily measured by means of any suitable apparatus which may be inserted into the urethra, as long as the surgeon can be certain that one end of the device is positioned at the juncture of the bladder and the urethra (i.e., the UVJ). The simplest means of obtaining this measurement is to provide graduations along at least a portion of the length of Foley catheter 14, as shown

in Fig. 17. In this fashion, when the balloon of the Foley is properly inflated within the bladder and the catheter pulled outwardly to ensure proper seating of the balloon at the juncture of the bladder and the urethra, the length of the urethra can be determined using the graduations which will be readily visible immediately adjacent the end of urethra 2. While the average urethra is 3 cm in length, this can often vary between about 2.7 and about 3.3 cm. As will be more fully understood below, the suture template employed in the method of the present invention can thus be manufactured in different sizes to accommodate the differing urethra lengths. A minimum of two sizes for the template may be provided, and more preferably at least three different sizes. Alternatively, the graduations may be employed to facilitate proper placement of a single-sized template.

After the placement of Foley catheter 14 and drainage of bladder 1, an infra umbilical incision is made in the patient in order to provide access to the pre-peritoneal region (the area between the abdominal wall and the peritoneum), and more particularly space of Retzius 8. Surgical dissection of space of Retzius 8 is necessary in order to provide visual access to the pubic bone for placement of the bone anchors. Thus, dissection is performed below the fascia, thereby eliminating the adventitial or supportive connective tissue in space of Retzius 8. Although dissection of the connective tissue in space of Retzius 8 can be accomplished in the typical fashion through a laparoscope, Applicant has found that a balloon dissection procedure is simpler and more effective.

Balloon dissection can be accomplished using the SPACEMAKER surgical balloon dissector manufactured by General Surgical Innovations of Portola Valley, California, and described in U.S. Patent No. 5,496,345, which is herein incorporated by reference. Other equivalent devices can also be employed for this purpose. The SPACEMAKER has a guide rod to which a small balloon is attached. The guide rod is inserted into the infraumbilical incision until the tip of the rod reaches the pubic symphysis in the space of Retzius (i.e., between the symphysis and the bladder). The balloon is then inflated in space

of Retzius 8 by filling the balloon with approximately 300cc of saline solution or other suitable fluid, thereby further deflating bladder 1 and separating the surrounding connective tissue in order to provide sufficient room in space of Retzius 8 for the fixation procedure of the present invention. The balloon is then aspirated and removed from the pre-peritoneal region.

Although the SPACEMAKER device has an integral trocar sleeve which may normally be left in the infraumbilical incision for placement of the laparoscope, the only size currently available is too small for the procedure of the present invention. Obviously a properly sized integral trocar sleeve could remain in the patient after removal of the deflated balloon. Alternatively, and as presently preferred, the SPACEMAKER device is removed in its entirety, and a larger 12mm trocar is inserted into the infraumbilical incision. A 12mm WOLF operating/laser laparoscope (preferably with a WOLF 50/50 beamsplitter camera) is inserted into the trocar sleeve. The pre-peritoneal region is then insufflated, preferably with CO<sub>2</sub> at a pressure between about 10 and about 30 mm Hg, thereby further expanding the space of Retzius and providing excellent laparoscopic vision in this region.

Although the balloon dissection procedure is highly effective, further dissection of the space of Retzius is typically necessary in order to provide the necessary access to the pubic bone and the periurethral tissue. Although this may be accomplished by means of a CO<sub>2</sub> laser or a electrocautery device through the laparoscope already inserted, it is presently preferred that an additional 5mm trocar be inserted in the midline suprapubically. An irrigation/suction/bovie device (such as that manufactured by US Surgical) is then inserted into the space of Retzius through the smaller trocar sleeve. It should be noted that the trocar sleeve, like the operative channel of the laparoscope, is cannula through which surgical instruments may be inserted. The irrigation/suction/bovie device will not only assist in further dissection of the space of Retzius, but will also provide the necessary irrigation and suction while the other instruments necessary for performing the present procedure are

employed through the infraumbilical trocar sleeve. The result of further dissection is that vision far superior to the standard MMK or Burch procedures employing a full abdominal incision will be provided, since it is difficult in these procedures for the surgeon to see the underside of the pubic bone where the anchors must be placed without the surgeon placing his or her head on the stomach of the patient. In this fashion, unobstructed laparoscopic access to the pubic bone and the periurethral tissue necessary for performing the procedure of the present invention is provided.

B. Creation of Bore in Pubic Bone

It should initially be noted that the procedure of the present invention may be employed with any of a variety of bone anchors, provided that the anchor can be readily secured to the pubic bone and a suture can be attached thereto. It is presently preferred, however, that the MITEK bone anchors disclosed in U.S. Patent No. 5,207,679 (herein incorporated by reference) be employed for this purpose. As discussed more fully herein, these anchors are secured in place by pressing them into properly-sized bores created in the pubic bone. Additional types of anchors include those disclosed in U.S. Patent No's 5,522,845, 5,520,696, 5,192,303 and 5,527,342 (all of which are herein incorporated by reference). The Acufex Microsurgical, Inc., subsidiary of the American Cyanamid Co., of Stamford, Connecticut also manufactures yet another type of anchor which may be employed in the surgical procedure of the present invention. Known as TAG anchors, the Acufex anchors are disclosed in U.S. Patent No's 5,258,016, 5,100,417 and 5,224,946, which are also incorporated herein by reference. Yet another suitable bone anchor is that sold by Li Medical of Boston, MA.

All of the above anchors are secured to bone by insertion into a bore previously created in the bone. Thus, the MITEK-MMK and related procedures require the use of either a mechanical drill or hand-operated awl in order to provide the bore for insertion of a bone anchor (such as those manufactured by

Mitek Surgical Products, Inc.) into the pubic bone. While these devices may be readily employed with large abdominal incisions, they cannot be used through a laparoscope for a number of reasons. Most importantly, these tools must be sufficiently sharp to enable the surgeon to penetrate the hard outer layers of the pubic bone (periosteum and cortical bone). Since the field of vision through a laparoscope may be limited at times, however, it is very risky to employ such sharp implements as there is a tremendous risk of puncturing the bladder or other soft tissue in the operative area. In addition, as best shown in Fig. 12, pubic bone 12 falls away from the laparoscope at an angle of approximately 45°. The angularity of pubic bone 12 therefore provides vision and operative difficulties which are overcome by the apparatus and methods of the present invention. Simply drilling into pubic bone 12 using prior art apparatus through the laparoscope is not advisable because the drill or awl tip will tend to slide downwardly during the drilling operation because of the manner in which pubic bone 12 angles downwardly away from the laparoscope. While the drill tip may eventually penetrate the hard outer periosteum of the bone, the drill may enter at an improper location or angle due to downward slippage of the drill tip. Ideally one would like to produce a bore in pubic bone 12 which is at an angle of approximately 45-degrees to the surface of the bone into which the bore is produced. This angle may, however, be between about 20 and about 60-degrees, to thereby provide sufficient support for the bone anchor to be placed in the bore thus produced.

Applicant has developed a novel method and apparatus for creating the required bores in the pubic bone through a laparoscope. The method and apparatus avoid the use of any sharp tips, while still enabling the surgeon to properly place the bores in the pubic bone without a risk of misalignment during the bore creation process. In order to produce the bore without a need for a sharp instrument, a laser is first employed to produce a cone-shaped crater in the pubic bone at the desired bore location. The crater is produced in the periosteum and cortical bone, thereby providing access to the soft cancellous,

or trabecular, bone. In this fashion, a drill tamper tool (to be described further herein) may then be employed to create the properly-sized bore.

5 In order to create the starter "crater" in the pubic bone, a CO<sub>2</sub> laser (such as a SHARPLAN 20 watt) is inserted through the laparoscopic channel, and is employed to create a cone-shaped crater slightly larger than the diameter of the laser beam in the pubic bone on either side of the pubic symphysis. The diameter of the laser beam is preferably about 2mm, and therefore the cone-shaped crater created in the pubic bone is slightly larger than 2mm in diameter. The crater should be sufficiently deep to reach the cancellous bone. A crater is established on either side of the pubic symphysis directly above and approximately 1cm lateral to the periurethral fascia at the UVJ. Fig. 21 depicts the space of Retzius after creation of bores 9 and 17 in pubic bone 12 on either side of pubic symphysis 7. The desired placement location can be readily determined through means of the optics of the laparoscope, as proper dissection of space of Retzius 8 will provide sufficient vision for proper identification of the appropriate structures in the patient. If needed, the surgeon may use one or more fingers to press upwardly on the periurethral tissue on either side of the urethra within the vagina in order to properly position the two starter craters in the pubic bone.

20 Once access to the cancellous bone has been provided by the cone-shaped craters created on either side of the pubic symphysis using the laser, the bore for insertion of the anchor may be readily created using the drill tamper tool of the present invention. Since the cancellous bone is significantly softer than the periosteum or cortical bone, it is not necessary that a sharp awl or drill bit be used to create the bore. Rather, a bluntly pointed drill tamper tool may be used, wherein the end of the tamper tool is not sufficiently sharp to puncture the bladder or other soft tissue under normal use. This provides a significant advantage in that damage to the bladder or other soft tissue structures in the patient may be readily avoided, and drill guides and the like which must be used with the MITEK instruments and similar apparatus can be avoided. As will be

25

30

understood, the MITEK drill guides cannot possibly be employed laparoscopically. The laser employed to create the cone-shaped craters can be readily aligned in the proper location, without risk of slippage or other inadvertent movement during the procedure. The laser-created craters can then be readily employed to insure that the bores for anchor placement are created in the exact, desired location.

One embodiment of the drill tamper tool of the present invention is shown in Fig.'s 5-7, and comprises an elongate rigid member 20 having a distal end which comprises a conical boring tip 21. End 22 of conical boring tip 21 preferably has a cross section similar in size and shape to the crater created in the pubic bone by the laser. In this fashion, alignment of conical boring tip 21 within the crater will be relatively easy. It is also preferred that end 22 of conical boring tip 21 be blunt so that it will not penetrate soft tissue such as the bladder during normal use (i.e., not sufficiently sharp to penetrate soft tissue or organs during normal use). Certainly, however, conical boring tip 21 should be sufficiently thin and blade-like to permit boring tip 21 to create the bore in the soft cancellous bone by use of hand force through the laparoscope. In this regard, conical boring tip 21 is preferably shaped similar to a flat bladed screwdriver. Thus, boring tip 21 has tapered side surfaces 23 and 24 which terminate in portion 25 which is of a circular cross-section. The diameter of circular/cross-section portion 25 is identical to the diameter of the bore which will be created in the pubic bone. By rotating the drill tamper tool while simultaneously pressing boring tip 21 into the crater in the pubic bone, the desired bore will be readily created therein. The diameter of portion 25 is also approximately the same as the body of the anchor to be inserted into the bore.

In order to ensure sufficient support for the bone anchors of the present invention, it is also important that the anchor be seated deep within the pubic bone. In order to ensure proper depth of the bore, therefore, collar 26 is provided on the drill tamper tool. Collar 26 is of a larger diameter than conical boring tip 21, and therefore will act as a stop preventing further penetration of the

drill tamper tool into the bone. Although collar 26 is shown as tapering in diameter between conical boring tip 21 and intermediate portion 27, it is also possible that collar 26 simply comprise a non-tapered end of intermediate portion 27. Intermediate portion 27 has a diameter significantly greater than that of  
5 conical boring tip 21, and is positioned on the opposite end of collar 26. Intermediate portion 27 not only allows the provision of collar 26, but also adds rigidity to the tamper tool. Intermediate portion 27, however, should be significantly smaller in diameter than the operative channel of the laparoscope so that sufficient vision of the operative region is provided. Preferably, the length  
10 of conical boring tip 21 is between about 1, and 3 cm, and most preferably about 1.4 cm. Intermediate portion 27 is preferably between about 2, and 6 cm, and most preferably about 5 cm.

In order to provide stability during the boring procedure, cylindrical guide portion 28 is also included on the drill tamper tool. Guide portion 28 has first end  
15 29 and second end 30. First end 29 is attached to intermediate portion 27 at the opposite end of collar 26. Cylindrical guide portion 28 preferably has a diameter slightly less than the operative channel of the laparoscope. In this fashion, guide portion 28 provides the necessary stability within the laparoscope to ensure proper placement of the bores. Second end 30 of guide portion 28 is preferably  
20 attached to handle 31. While handle 31 is shown as having a flat end portion 32 and curved hand grip surfaces 33, handle 31 can be of a variety of forms and still be sufficient for purposes of the present invention. Handle 31 facilitates the proper manipulation of conical boring tip 21 through the laparoscope, and provides a sufficiently firm surface 32 upon which force may be applied to  
25 complete the boring operation. Guide portion 28 preferably has a length between about 50 and about 55 cm, and most preferably about 52 cm. The overall length of the drill tamper tool therefore permits sufficient access to the pubic bone, while also providing an ergonomically-effective boring operation through the laparoscope and ensuring that the tool does not interfere with the  
30 anesthesiologist.

Figures 44-45 depict an alternative embodiment for the drill tamper tool of the present invention wherein the intermediate portion has been eliminated. Thus, the drill tamper tool of Fig. 44 comprises an elongate, rigid shaft 328, which corresponds to the guide portion in the embodiment of Fig's 5-7. At one end of shaft 328 is handle 331 which serves the same purpose as described previously. At the opposite end of shaft 328 is boring tip 321. Boring tip 321 is as described previously, and thus has blunt end 322, circular cross-section portion 325, and tapered side surface 323 (the opposite tapered side surface is not visible). Collar 326 is positioned between boring tip 321 and shaft 328, and once again acts as a stop to limit penetration to the desired depth. Collar 326 is preferably tapered as shown in order to provide sufficient laparoscopic vision. Boring tip 321 has a length of between about 1 and about 3cm, preferably about 1.4 cm. Shaft 328 has a length of between about 45 and about 60 cm, preferably between about 50 and about 52 cm, thereby providing laparoscopic access to the pubic bone. Shaft 328 also preferably has a diameter which is only slightly less than the operative channel of the laparoscope in order to provide stability and prevent insufflation gas from escaping. While end 322 of tip 321 may be blunt as previously described, in the embodiment of Figs. 44-45 it has a pointed tip.

#### C. Insertion Of Bone Anchors In Pubic Bone

One preferred anchor for use in the present invention is shown in Figs. 3 and 4, and is identical to that disclosed in U.S. Patent No. 5,207,679. Anchor 9, which is preferably made of titanium alloy or other suitable material, has a cylindrical body 40 and a conical end 44 attached thereto. At least two flexible barbs 41 curve outwardly away from body 40. A groove 42 is provided on either side of body 40 at the end opposite to conical end 44. In addition, cylindrical end 45 extends away from body 40 adjacent groove 42. The longitudinal axis of cylindrical end 45 is aligned with the longitudinal axis of body 40. The diameter of cylindrical end 45 is preferably equivalent to the diameter of body 40 within grooves 42 positioned on opposite sides of body 40. As will be understood below, this structure facilitates the attachment of anchor 9 to an insertion tool.

As best shown in Fig. 4, body 40 and cylindrical end 45 have an aperture 43 provided therethrough. Aperture 43 is sized so as to accommodate a suture appropriate for the fixation procedure of the present invention. It is preferred that a size 0 GORE-TEX suture be employed, and thus anchor 9 and its accompanying aperture 43 should be sized accordingly. The use of a GORE-TEX suture is preferred for reasons of strength and non-elasticity. Certainly other types of sutures could be employed if necessary. A portion of suture 10 is shown in Fig. 3 having been inserted through aperture 43.

The insertion of anchor 9 is relatively straightforward, and merely requires that the anchor be pressed completely into the bore which has previously been created in the pubic bone. Preferably, anchor 9 is inserted into the bore in the pubic bone until conical end 44 reaches the distal end of the bore. The bore should be at least as long as the length of anchor 9, however, it is preferably considerably longer to ensure sufficient support for the anchor. As anchor 9 is pressed into the bore, flexible barbs 41 will be compressed against body 40 as they are inserted past the hard periosteum and cortical bone surrounding the bore. Once within the bore, however, flexible barbs 41 will tend to spring back into the soft cancellous bone, thereby securing the anchor in place. A slight tug on the tails of the suture 10 will also cause barbs 41 to further deploy.

In order to insert anchor 9 into the bore previously created in the pubic bone, the anchor insertion tool shown in Fig's. 8-10 may be employed. Thus, after the drill tamper tool has been employed to create the necessary bores, the anchor insertion tool of the present invention having an anchor and threaded suture loaded there, is inserted into the laparoscope for proper seating of anchor 9.

The anchor insertion tool of the present invention comprises a rigid elongate member 50 having a handle 51 at one end, and an anchor-receiving tip 52 at the opposite end of elongate member 50. As was the case with the drill tamper tool, handle 51 can be of any variety, and that shown is only one

embodiment for this handle. Anchor-receiving tip 52 may be similar in construction to that shown in Figs. 4-6 of U.S. Patent No. 5,207,679. Anchor-receiving tip 52 is constructed so as to matingly receive anchor 9 in order to facilitate insertion of anchor 9 into the bore. As will be apparent, the longitudinal axis of anchor-receiving tip 52 should be aligned with the longitudinal axis of elongate member 50. Anchor-receiving tip 52 is cylindrical in nature, having a diameter approximately equivalent to body 40 of anchor 9. In this manner, at least a portion of anchor-receiving tip 52 may pass through the bore in the pubic bone during the anchor insertion process to properly seat the anchor completely within the bore.

Anchor-receiving tip 52 has a pair of guide tabs 53 extending from the end of anchor-receiving tip 52 on either side thereof. Guide tabs 53 are sized and shaped so as to be matingly received within grooves 42 positioned on either side of anchor 9. Anchor-receiving tip 52 also has a cylindrical slot 54 aligned with the longitudinal axis of tip 52. Cylindrical slot 54 should correspond in size and shape to cylindrical end 45 of anchor 9 in order to matingly receive the same. It is also preferable that the distance between guide tabs 53 be slightly smaller than the distance between the corresponding grooves 42 on anchor 9. In this fashion, guide tabs 53 as well as cylindrical slot 54 will apply compressive force against anchor 9 thereby more securely holding anchor 9 in place when loaded within anchor-receiving tip 52.

Since suture 10 will extend outwardly on either side of anchor 9, it is preferable to provide a means for ensuring that suture 10 is not abraded by the bone surrounding the bore during the insertion process. Thus, a pair of tapered grooves 55 are provided on either side of the anchor insertion tool, and extend from the end of anchor-receiving tip 52 along at least a portion of the length of elongate member 50. As best shown in Fig. 10 wherein anchor 9 has been loaded upon the insertion tool, grooves 55 ensure that the sutures will be protected by anchor-receiving tip 52 and a portion of elongate member 50 during the insertion process. Since any nicks in the suture may compromise the

strength and permanency of the fixation, it is important to ensure that the suture is not damaged in any fashion.

Anchor-receiving tip 52 should also be of the proper length to ensure deep placement of anchor 9 completely within the bore. Thus, the length of the combination of anchor-receiving tip 52 and bone anchor 9 when loaded in the manner shown in Fig. 10 should be equivalent to the size of the bore created in the pubic bone. Since the diameter of elongate member 50 is significantly greater than that of anchor-receiving tip 52, distal end 56 of elongate member 50 will firmly abut the pubic bone once the anchor has been completely inserted into the bore. In this manner, the surgeon can be certain that the anchor has been seated to its complete and proper depth.

As was the case with the drill tamper tool of the present invention, elongate member 50 further comprises an intermediate section 57 and a guide portion 58. Intermediate portion 57 should have a diameter sufficiently less than that of the laparoscope in order to provide adequate vision for the surgeon, and intermediate portion 57 also has distal end 56 described above. Preferably, intermediate portion 57 has a length between about 2 and about 6 cm, most preferably about 5 cm. It should be kept in mind that, as shown in Fig. 10, suture 10 will extend along the length of intermediate portion 57 on either side thereof. This consideration must be kept in mind when sizing the diameter of intermediate portion 57 to ensure not only that it can be easily inserted through the laparoscope, but also to ensure adequate vision.

Guide portion 58 will necessarily be slightly smaller than the diameter of the guide portion for the drill tamper tool previously described, since, as shown in Fig. 10, suture 10 will extend along either side of guide portion 58. With this in mind, the total of the diameter of guide portion 58 and twice the diameter of suture 10 should be only slightly less than the inside diameter of the operative channel of the laparoscope. In this fashion, guide portion 28 provides a rigid support for the surgeon during the anchor insertion process. Preferably, guide

portion 58 has a length between about 50 and 55 cm., most preferably about 52 cm. This provides an overall inserter length comparable to that of the drill tamper tool, thereby providing the same advantages with regard to the tamper tool length.

5           In order to effectively employ the procedure of the present invention laparoscopically, it is necessary that the two tails of suture 10 be controlled as much as possible. If the sutures are permitted to hang away from anchor 9 or the anchor insertion tool, the tails will generally become balled within the space of Retzius, thereby making the suture tying procedure difficult, if not impossible.

10       Although the sutures may be held against the anchor insertion tool by hand, Applicant has developed a more effective manner of accomplishing this. Thus, first and second shouldered depressions 59 and 60 are preferably provided about the circumference of guide portion 58. A small rubber band 61 (as shown in Fig. 10), or other suitable elastic band, may be held within each of the two

15       shouldered depressions, with the two tails of suture 10 held beneath rubber band 61 on either side of guide portion 58 as shown. First shouldered depression 59 is preferably positioned approximately 10 cm from the ends of guide tabs 53. Second shouldered depression 60 is preferably positioned about 40 cm from guide tabs 53. Both shouldered depressions act, in conjunction with an elastic

20       band contained therein, to hold suture 10 in place on the sides of the anchor insertion tool.

          In addition to holding the suture in place on the anchor insertion tool, the shouldered depression/elastic band combination further improves the laparoscopic procedure of the invention by not only assisting in seating the

25       anchor, but also in the suture retrieval process. As shown in Fig. 20, the anchor insertion tool of the present invention, with a pre-loaded anchor and suture assembly attached thereto, is inserted through the laparoscope for placement of the anchor as previously described. Once the anchor has been seated within the bore, the anchor insertion tool is then pulled outwardly utilizing handle 51

30       contained thereon. The combination of shouldered depressions 59 and 60 and

rubber band 61 act to provide tension in suture 10 which in turn pulls outwardly on anchor 9 which is now contained in the bore. This outward force on anchor 9 will cause flexible barbs 41 to extend outwardly into the cancellous bone surrounding the bore, thereby further securing anchor 9 in position. In other words, this outward force on suture 10 by the drag created by the shoulder depression/elastic band combination will act to deploy the previously compressed barbs 41 on anchor 9, thereby rigidly securing anchor 9 within the bore.

In order to facilitate the surgical procedure of the present invention, the drill tamper tool and the anchor-insertion tool described above may be provided in the form of a reusable surgical kit.

D. Fixation of Periurethral Tissue At the UVJ Via Suturing

Once the anchor and suture assembly have been secured within the bore created in the pubic bone, it is next necessary to utilize the two tails of the suture to elevate the periurethral tissue on the corresponding side of the urethra at the UVJ. Applicant has found that the most effective means for accomplishing this is to pull each tail of the suture through the periurethral tissue into the vagina. In this fashion, the two tails may then be easily tied to one another within the vagina to provide the necessary support, and eliminating any need for laparoscopic suture tying. Obviously, however, a means for retrieving the suture tails must be provided.

The method of suture retrieval is best shown in Fig. 20, which is a perspective view of the procedure with portions of the patient's anatomy cut-away for purposes of clarity. As shown in Fig. 20, as the anchor insertion tool of the present invention is partially withdrawn from the patient through the laparoscope, first shouldered depression 59 in combination with rubber band 61 will cause both suture tails to be tensioned between the anchor and the anchor insertion tool as shown. Were this not the case, the suture tails would merely fall into the space of Retzius similar to a ball of yarn, and thereby be difficult (if not

impossible) to retrieve. While the suture tails could be tensioned between the anchor and the anchor insertion tool by pulling outwardly on the sutures, this would unnecessarily require an additional pair of hands. Thus, the shouldered depression/rubber band combination is also effective in this regard.

5           Once the anchor insertion tool has been partially removed in order to tension the suture tails in the manner shown in Fig. 20, a suture retrieving tool may be inserted into the vagina and then pressed upwardly on one side of the urethra into the space of Retzius in order to retrieve one of the suture tails in the manner shown. Thus, the suture retrieving tool must have a sharp point capable  
10 of passing completely through the full thickness of the periurethral fascia and vaginal mucosa adjacent the urethra. The suture retrieval tool must also have a means for grasping the suture tail and pulling the tail back through the full thickness of the periurethral and vaginal mucosa by means of the same entry hole created by the sharp point. Each tail is pulled into the vagina in this fashion  
15 at the proper location. Preferably, one tail is pulled into the vagina approximately 1 cm from the urethra at the UVJ, and the other tail is pulled into the vagina approximately 2 cm lateral from the urethra. In other words, each tail penetrates the periurethral tissue along an imaginary line extending substantially perpendicularly away from the urethra. Each tail may then be pulled out of the  
20 vagina for purposes of tying.

          The suture tails are tied to one another using a series of standard surgeon's knots, and each knot is slid by hand to the point in the vagina at which the suture tails were previously retrieved. The tails are tied to one another in a sufficiently tight fashion so that suture 10 creates an upward force on the  
25 periurethral tissue adjacent the urethra in order to elevate the urethra at the UVJ and restore the urethra to its proper angle. The position of the urethra can be readily observed by the surgeon as this procedure is performed, thereby ensuring that the urethra is restored to the desired angle. The entire procedure (anchor insertion, suture retrieval, etc.) is then repeated for the anchor placed on  
30 the opposite side of the pubic symphysis, and the suture tails of that anchor are

pulled into the vagina through the periurethral tissue on the opposite side of the urethra as the first suture tails. Tying is then performed in the same fashion, thereby elevating the other side of the urethra to thereby completely restore the urethral angle at the UVJ.

5           The result of this process is best shown in Fig. 2, wherein it is shown that suture 10, and the corresponding suture on the opposite side of the urethra have restored the urethra to its proper angle. It should be noted that at no time do the sutures pull upward directly beneath the urethra, since doing so would create the risk that the suture would cause urethral blockage. After tying, the remaining  
10       tails of suture 10 are cut at the knot. After the suture tails have been cut adjacent to the knot, it is preferred that the knot be moved into the abdominal cavity. This can be accomplished merely by pulling lightly on one portion of the suture within the vagina, which thereby causes the suture to be pulled through one of the holes previously traded in the vaginal mucosa and periurethral fascia  
15       towards anchor 9. In other words, the suture acts much like a rope on a pulley system, such that when one portion of the tied suture is pulled downwardly into the vagina, the opposite side will traverse upwardly, carrying the knot with it into the abdominal cavity. In this manner, the knot will not be present within the vagina where it might cause irritation. The portion of suture 10 remaining in the  
20       vagina will epithelize within three to four days, and the patient will no longer sense that the sutures are in place. The result is a permanent fixation of the periurethral tissue on both sides of the urethra, thereby restoring the urethra to its correct angle and eliminating the SUI. After completion of the tying process, the surgical area within the patient is flushed with a dilute lidocaine solution, the  
25       laparoscope and trocars removed, a stronger lidocaine solution is applied to the incision sites, and the incisions are closed in the usual fashion. The Foley catheter may then be removed, and the patient permitted to recover in the usual fashion. Normal everyday activities may be resumed within 2-3 days.

### E. Suture Retriever

In order to pull the tails of suture 10 through the entire thickness of the periurethral fascia and vaginal mucosa, various tools can be employed. For example, a U.S. Surgical Auto-Stitch tool may be effectively employed for this purpose. It is critical, however, that the tool employed being capable of readily be inserted through the periurethral tissue from the vagina into the space of Retzius, while also being capable of grasping the suture tails. It is also critical that the surfaces contacting suture 10 be perfectly smooth in order to eliminate the risk of nicks or cuts in suture 10 which would obviously compromise the effectiveness of the procedure. Applicant has developed a novel suture retriever for accomplishing this purpose which provides a convenient and simple means of retrieving the suture tails.

The suture retrieval tool of the present invention is depicted in Fig. 11, and comprises metal retrieving end 65, midshaft 66, and handle 67. Midshaft 66 and handle 67 may be singularly molded from polycarbonate or a similar FDA-approved material in the typical fashion. As shown in Fig. 12, handle 67 is also preferably knurled in order to facilitate grasping and manipulation of the retriever. Metal retrieving end 65 is preferably made of stainless steel and can be securely molded into distal end 68 of midshaft 66.

Metal retrieving end 65 comprises a rigid, rod-like shaft 69, and a sharp tip 70 capable of penetrating the periurethral tissue. The diameter of distal end 68 is preferably significantly greater than that of shaft 69, and will act as a stop in order to limit the penetration of the suture retrieval tool into the space of Retzius. Thus, the length of shaft 69 and tip 70 may be selected so as to ensure that when the suture retrieval tool is inserted into the space of Retzius through the vagina that sharp tip 70 will generally be incapable of striking any surrounding soft tissue.

Retrieving end 65 further comprises a return leg 71 which extends away from sharp tip 70 in the same direction of shaft 69. Shaft 69, return leg 71 and the underside of sharp tip 70 thus create an inverted U-shaped region capable of ensnaring suture 10 for retrieval purposes. The distance between return leg 71 and shaft 69 in the region of the inverted U-shape is preferably approximately the same diameter as suture 10. In this fashion, and as shown in Fig. 20, after sharp tip 70 has penetrated the periurethral tissue adjacent the vagina in order to enter the space of Retzius, the inverted U-shape may be pulled downwardly over a suture tail, thereby snaring the suture. Metal retrieving end 65 may then be pulled back through the periurethral tissue, and the tail of suture 10 will remain snared between return leg 71 and shaft 69 directly beneath sharp tip 70. Although the suture tail will slide within the U-shaped region, it will nevertheless be pulled into the vagina.

One critical feature of the suture retriever of Fig. 12 is that the inner surfaces of metal retrieving end 65 which contact suture 10 must be rounded and smooth in order to permit suture 10 to freely slide within the inverted U-shaped portion as the retriever is withdrawn. This prevents nicking or fraying of the suture while still permitting the suture tail to be withdrawn. Thus, the only sharp portion of metal retrieving end 65 is sharp tip 70.

While it is possible that handle 67, midshaft 66, and metal retrieving end 65 may all be positioned along the same longitudinal axis thereby forming a rigid, elongate structure, Applicant has found that the process of the present invention can be simplified if the elements of the retriever have the angular relationship indicated in Fig. 11. This is particularly true when the template of the present invention (to be described further herein) is employed. Thus, in the embodiment of Fig. 11, metal retrieving end 65 preferably is positioned at an angle of between about 100 degrees and about 130 degrees, most preferably about 120 degrees, to midshaft 66 (this angle is indicated as A in Fig. 11). Likewise, handle 67 is preferably positioned at an angle of between about 100 degrees and about 130 degrees, most preferably about 120 degrees, to midshaft 66 (this angle is

indicated as B in Fig. 11). Thus, the longitudinal axis of shaft 69 of metal retrieving end 65 will be parallel to the longitudinal axis of handle 67. In this fashion, when the retriever of the present invention is employed midshaft 66 will generally be positioned parallel to the longitudinal axis of the vagina. Metal  
5 retrieving end 65 will then extend upwardly through the periurethral tissue into the space of Retzius as desired. As best shown in Fig. 20, handle 67 will thereby extend downwardly outside of the vagina, and thus sharp tip 70 may be readily forced through the periurethral tissue as desired merely by pushing upwardly on handle 67.

10 As shown in Fig. 11, the transitions between handle 67 and midshaft 66 as well as between midshaft 66, and retrieving end 65 should be gently curved in order to ease placement. It should be noted that angles A and B can vary significantly, however it is preferred that they be as close to one another as possible so that the parallel relationship of handle 67 and retrieving end 65 is  
15 maintained. In addition, the present configuration ensures that the retrieving end 65 will enter the space of Retzius at an angle of approximately 90 degrees to the tensioned suture tails (i.e., the suture tails tensioned between the anchor and the anchor insertion tool). This parallel relationship allows for effective snaring of the suture, as well as improved vision of the retrieval through the laparoscope.

20 Preferably, midshaft 66 is between about 2 and about 6 cm. in length, most preferably about 4 cm. The cross-sectional area of midshaft 66 should merely be a size chosen to provide the necessary rigidity while also not blocking vision within the vagina during the procedure. Likewise, handle 67 is preferably about 4 cm long, however the length is not as critical since handle 67 remains  
25 completely outside of the body. The diameter of handle 67 should be chosen so as to provide a comfortable and secure means of grasping the suture retrieval tool. Preferably, handle 67 is about 3 cm in diameter.

An alternative, and presently preferred embodiment for the suture retrieval tool of the present invention is shown in Figs. 46-48. In this embodiment, the

suture retrieval tool once again comprises metal retrieving end 265, a midshaft 266 and a handle 267. The longitudinal axis of these three elements are as shown by the dashed lines. Midshaft 266 and handle 267 may be singularly molded from polycarbonate or a similar FDA-approved material in the typical fashion. Handle 267 preferably is curved in the manner shown so as to provide a comfortable grip for the surgeon.

Metal retrieving end 265 comprises a rigid, rod-like shaft 269 and a tip of portion 270. As best shown in Fig. 47, tip portion 270 is preferably flat in nature, and, as shown in Fig. 48, has a width L which is less than the width or diameter of shaft 269. Tip 270 has a sharpened distal end 274, and a suture slot 271 located approximately of the distal end. Slot 271 also has an entrance 275 thereto, and entrance 275 is spaced inwardly from shaft 269. In other words, the center line of tip portion 270 is slightly off-set from the longitudinal axis of shaft 269. In this manner, a suture may be snared in the manner described previously by allowing the suture to enter entrance 275 until it rests within slot 271. When the tip of the suture retrieval tool is then retracted back into the vagina, the off-set between opening 275 and shaft 269 will ensure that leg 276 adjacent suture slot 275 will not snag against the patient's tissue. In other words, since shaft 269 tends to create a puncture hole in the patient's tissue which is greater than the width of tip 270, the tip will not snag on the edges of this puncture hole.

In addition, shaft 269 preferably has a diameter which is significantly greater than that of the suture employed. In this manner, shaft 269 will create a puncture hole in the soft tissue which is larger than the knot in the suture. In this manner, the knot may be moved from the vagina into the abdominal cavity of the patient through this puncture hole in the manner previously described. In order to facilitate insertion of shaft 269 into the patient, tapered walls 277 are provided. Tapered walls 277 provide a smooth transition between flat tip 270 and rounded shaft 269.

In the embodiment of Figs. 46-48, the angular arrangement of retrieving end 265, midshaft 266 and handle 267 is preferably modified somewhat from that previously described in that the angle between midshaft 266 and retrieving end 265 is greater than that previously described. Applicants have found that by opening this angle further, the surgeon will be better able to avoid striking blood vessels on the undercarriage of the pubic bone with the sharp distal end 274. Thus, while angle M between midshaft 266 and handle 267 is preferably between about 120 degrees and about 135 degrees, the angle between retrieving end 265 and midshaft 266, however, is between about 135 degrees and about 155 degrees, more preferably about 150 degrees. In order to add strength and rigidity, a small extension to 278 on midshaft 266 has a longitudinal axis corresponding to that of retrieving end 265. Extension 278 may be hollow, thereby allowing retrieving end 265 to be inserted and secured therein. The diameter of extension 278, as well as the remainder of midshaft 266, is preferably larger than that of shaft 269. This allows end 268 of extension 278 to act as a stop which prevents the midshaft from penetrating the soft tissue once the retrieving end is inserted through the soft tissue of a patient.

#### F. Surgical Template

While the placement of the sutures at the UVJ may be accomplished by merely feeling for the correct location within the vagina by hand, particularly in relation to the ball of the Foley catheter, Applicant has developed a novel template which greatly simplifies proper placement of the sutures. This device not only prevents bladder injury, urethral injury, or vascular accidents, the template also ensures a proper distance between the two suture tails to ensure that there is adequate periurethral tissue between the tails to provide the necessary support. Obviously if the suture tails are placed too close to one another, there is a risk that the suture will tear through the periurethral tissue and eliminate the fixation. Thus, a template is provided wherein the template has at least two apertures which may be properly positioned on either side of the urethra. The suture retriever may then be inserted through these apertures and

thereafter through the periurethral tissue in order to snare the suture tails in the manner described previously.

One embodiment for the surgical template is depicted in Figs. 13-17. The template comprises a trough 80 of arcuate cross-section, wherein trough 80 is sized so as to cradle the patient's urethra when properly positioned. First and second wing members 81 and 82 extend away from opposite sides of trough 80, preferably perpendicularly to the longitudinally axis of trough 80 in the manner shown. Most preferably wing members 81 and 82 extend perpendicularly away from opposite sides of trough 80 at the upper most edges 83 and 84 of trough 80. First and second suture guide apertures 85 and 86 are positioned in each of the wing members 81 and 82 as shown. The guide apertures are positioned so that when the urethra of the patient is properly positioned within trough 80, guide apertures 85 and 86 on each wing will indicate the proper location for the sutures. First suture guide aperture 85 is positioned so that the first tail of suture 10 will penetrate the periurethral tissue approximately 1 cm from the urethra adjacent the UVJ. Second guide aperture 86 is preferably positioned about 1 cm further away from the urethra along a line perpendicular to the longitudinal axis of trough 80. In other words, the distance between first suture guide aperture 85 and second suture guide aperture 86 is preferably about 1 cm. In this manner, the surgeon can be confident that sufficient periurethral tissue will be present between the two suture tails.

It is certainly possible that the template of the present invention may merely be held in place by hand, and in fact the downwardly sloping nature of the underside wing members 81 and 82 are suitable for placement of the surgeon's fingers thereunder. Additional alignment means are preferably provided, however at a minimum, end wall 87 is provided at the end of trough 80 furthest away from the suture guide apertures. Thus, as long as the template is properly sized for the length of the patient's urethra, the surgeon may hold the template in place with end wall 87 abutting the outermost end 89 of urethra 4 in order to ensure proper alignment. For example, if the length of the patient's urethra is

determined to be three cm, the distance between end wall 87 and first and second guide apertures 85 and 86 should be between about 2.5 and about 3.2 cm, most preferably about 2.8 cm. The guide apertures should also be between about 0.25 and about 0.5 cm from distal end 91 of the wing members (Fig. 13).  
5 As long as the template is positioned with end wall 87 abutting the outermost portion of the urethra, the surgeon will be assured that the sutures will be properly placed without risk of puncturing the bladder, or urethra.

While the surgeon may employ two fingers beneath wing members 81 and 82 to hold the template in the proper position, Applicant has found that the  
10 provision of arcuate alignment member 88 secured to end wall 87 may be effectively employed for securing the template in place without the need for the surgeon to hold the template in any manner. Alignment member 88 is preferably positioned parallel to trough 80, with the center line of alignment member 88 aligned with the center line of trough 80. Alignment member 88 may either  
15 extend away from trough 80 as shown in Fig. 13, or alternatively may extend away from end wall 87 directly along the interior of trough 80 as shown in Fig. 18

When the embodiment of Figs. 13-16 is employed, alignment member 88 is preferably sized so that when the template is manufactured from a resilient material, alignment member 88 may be rigidly snapped about Foley catheter 14  
20 as shown in Fig. 20. Thus, the shaft of Foley catheter will be securely held within alignment member 88, and the surgeon need only pull outwardly on the Foley catheter while sliding the template into the vagina towards the urethra until end wall 87 abuts end 89 of urethra 2. The ball of the Foley catheter will thus be positioned at the UVJ, and the template will likewise be positioned at the  
25 appropriate location assuming that a template of the proper size has been selected based upon the length of the urethra.

As an alternative to providing various sizes for the template of the present invention, a single, larger-sized template may be employed provided that alignment member 88 is snapped about the shaft of Foley catheter 14 in the

proper location. Thus, instead of abutting end wall 87 against end 89 of urethra 2, end wall 87 is instead aligned with the appropriate graduation along the shaft of Foley catheter 14 based upon the previously-measured length of the urethra. Likewise, end 90 of alignment member 88 could alternatively be aligned with the appropriate graduation along the shaft of Foley catheter 14 in order to provide the proper placement of the template based upon the length of the patient's urethra.

Fig. 18 depicts yet another alternative embodiment for the template of the present invention in which alignment member 88 extends along the interior of trough 80. In employing this embodiment, alignment member 88 is inserted into the urethra along with Foley catheter 13 until end wall 87 of the template abuts end 89 of urethra 2. As will be understood, therefor, an appropriately-sized template will ensure proper placement of the sutures.

Figs. 42-43 depict an alternative embodiment for the surgical template of the present invention. As was the case in the embodiment of Figs. 13-16, alignment member 388 extends away from trough 380. In this embodiment, alignment member 388 is tubular in nature. In addition, the longitudinal axis of alignment member 388 is positioned slightly above the longitudinal axis of trough 380. This spacing provides for more proper alignment of the template. Instead of rigidly snapping about a Foley catheter, a Foley catheter may merely be slide into alignment member 388 and held in place by friction or other suitable adhesive means. Preferably, the template of Figs. 42-43 is provided to the surgeon with a Foley catheter already extending through alignment member 388. Preferably, alignment member 388 is sized so as to snugly hold the Foley catheter therein. In addition, the template is provided with the Foley catheter located at the desired location.

Wing members 381 and 382 are once again provided, along with first and second guide apertures 385 and 386 therein. In order facilitate the insertion of the tip of a suture retrieval tool through these apertures, grooves 390 are

provided on the underside of each wing. Grooves 390 extend parallel to the longitudinal axis of trough 380, and preferably extend between the apertures and the front edge 393 of each wing. In this fashion, the tip of the suture retrieval tool may be slid along grooves 380 until it reaches the desired aperture. A bevel 391 is also provided on the side of the aperture adjacent grooves 390. Bevel 391 permits the retrieving end of the suture retrieval tool to be moved to a more acute angle with respect to the wing member during the retrieval process. A similar bevel 391 is provided on the upper surface of each wing member adjacent each aperture. Bevels 391 on the upper surface of the wing members extend from the opposite side of each aperture as the bevels on the under surface of the wing members. This further ensures that the retrieving end of the suture retrieval tool can be moved to an acute angle with respect to the wing members.

Finally, the template of the present invention can be manufactured of any suitable material such as polycarbonate or other FDA-approved plastic. The template may be readily molded using known technology, and is preferably manufactured as a disposable, single-use item. The drill tamper tool and anchor insertion tools, on the other hand, should be made from medical-grade stainless steel. The handles, however, may be polycarbonate or other FDA-approved plastic.

#### 20 G. Alternative Anchor and Anchor-Insertion Tool

As mentioned previously, and as best shown in Fig. 19, pubic bone 12 falls away from the laparoscope at an angle of about 45° to 60°. Thus, it is impossible to create a bore in the pubic bone which extends perpendicularly from the surface of the bone. Thus, the bore produced in pubic bone 12 extends inwardly at an angle of between about 20° and about 60°. In other words, as shown in Fig. 23 which is a cross-sectional view of pubic bone 12, when bore 13 is viewed in cross-section as shown, the angle between surface 100 of the pubic bone and bore 13 at X will be between about 20° and about 60°, preferably about 45°. During the laparoscopic surgical procedure of the present invention, the

surgeon may readily modify angle X in order to provide an angle which corresponds to that of the anchor to be described (preferably about 45°). This may be accomplished by inflating or deflating the abdominal cavity as needed in order to change the angle of the laparoscopic channel in relation to the pubic bone. Since interior surface 102 of cortical bone 101 is parallel to outer surface 100 of pubic bone 12, this same angular relationship will exist within the interior of the bore. When an anchor such as that disclosed in Fig's 3 and 4 is employed, one will immediately recognize that this angular relationship of surface 102 and bore 13 will only permit the lower barb of the anchor to contact surface 102. Since cancellous (or trabecular) bone 103 offers very little support for the anchor, only the contact between the lower most barb of the anchor of Fig's 3 and 4 and surface 102 provides the principle support which prevents the anchor from being pulled out of the bore.

When anchors of the type shown in Fig's 3 and 4 are tested for pull-out strength, they are typically pulled only in the direction of arrow B. After the urethropexy procedure of the present invention is accomplished, however, any force on the anchor is most often in the direction of arrow A. As will be readily understood, due to that fact that only the lower barb will be in contact with surface 102, it is possible for the anchor to be pulled out of the bore due to forces acting in the direction of arrow A. This results from the fact that the end of the anchor to which the suture is secured is able to pivot downwardly in the direction of Arrow A since cancellous bone 103 offers little support.

In order to overcome the problems of the prior art anchor designs noted above, the present applicant has developed a new anchor design shown in Fig's 23-30. The shortcomings of the prior art are overcome by modifying the orientation of the wing members or barbs to ensure that the external ends of the wing members (i.e., the portions which contact inner surface 102 of the cortical bone) have an angular relationship corresponding to the angular relationship between bore 13 and surface 102 (to be further described in detail below). Thus, as best shown in Fig's 24 and 25, anchor 139 comprises cylindrical body 140, at

least three wing members (barbs 141, 142 and 143), and aperture 150 positioned in tab member 151. Body 140 is similar to that of the prior art designs, however distal end 160 may be rounded since it is relatively easy to urge distal end 160 into cancellous bone as needed. The conical shape of the prior art design, however, will certainly work. Proximal end 161 is preferably perpendicular to longitudinal axis 162 of body 140 to thereby provide a flat proximal end surface which may cooperate with the new anchor-insertion tool to be described herein. Aperture 150 serves the same purpose described previously (i.e., a means for attaching a suture to the anchor), and once again the surfaces and edges of aperture 150 should be as smooth as possible to prevent fraying of the suture. In fact, aperture 150 may even be highly polished or even coated to reduce friction.

Tab member 151, as shown in Fig's 24-26, preferably has a height 163 corresponding approximately to the diameter of body 140 and a width 164 less than the diameter of body 140. The length 165 of tab member 151 should be sufficient for aperture 150 to permit a size 0 suture to be passed therethrough. It is also preferred that the length of tab member 151 extend perpendicularly away from proximal end 161 to facilitate cooperation and mating with the anchor-insertion tool to be described.

As mentioned above, the most significant feature of the anchor shown in Fig's 23-30 is the arrangement of the wing member or barbs. As is the case with the prior art anchor design, the barbs may be elastically flexed (i.e., have memory) from the normal deployed position (as shown in the figures), to a compressed position. In the deployed position, the barbs preferably curvilinearly extend radially and axially away from body 140, as shown. In the compressed position, the barbs are substantially straightened to permit insertion of the anchor into a bore created in bone in the manner of the prior art (see, for example, U.S. Patent No's 5,207,679 and 5,217,486 both of which are herein incorporated by way of reference). To facilitate compression and insertion, a plurality of channels 170 are provided along the length of body 140. One of channels 170 is

positioned beneath each of the wing members, and is aligned therewith. Each of the channels is further sized so as to accept at least a portion of, and preferably the entirety of the corresponding wing member aligned therewith. In this manner, when a wing member is compressed during the anchor insertion  
5 process, the compressed and straightened wing member will be positioned entirely within channel 170 positioned adjacent the wing member.

With the wing members in this compressed state, the diameter of the anchor will be equivalent to that of body 140, thereby permitting the anchor to be inserted into a bore having a diameter only slightly greater than body 140. As the  
10 wing members extend into the bore beyond interior surface 102 of the cortical bone, the wing members will return to their deployed position, since the cancellous bone is not sufficiently hard to resist the spring-back of the wing members due to their inherent elasticity (or memory). As shown in Fig. 23, since the diameter of bore 13 is only slightly greater than body 140, the external ends  
15 of the wing members will abut against interior surface 102 thereby preventing removal of the anchor from the bore. For example, external end 144 of barb 141 is shown in Fig. 23 as resting against interior surface 102.

The cross-sectional profile of channels 170 is shown in Fig. 30, which is a cross-sectional view of the anchor of Fig. 26. As shown in this view, channels  
20 170 are preferably sufficiently deep to permit an entire wing member to be compressed into the channel. In addition, as shown in Fig. 24, the length of each channel 170 is only sufficiently long to contain the entire corresponding wing member when the latter is compressed. Thus, channels 170 may be of different lengths depending upon the various lengths of the corresponding wing members.  
25 End 171 of channel 170 (see Fig. 24) may also be angled in relation to the longitudinal axis 162 as shown in order to correspond with the external ends of the wing members, should these external ends be angled in the manner to be described.

In order to ensure that at least a portion of the external ends of each wing member contacts interior surface 102 of the cortical bone adjacent bore 13 when bore 13 is positioned non-perpendicularly to outer surface 100 of the pubic bone, at least a portion of the external end of each wing member is aligned along first imaginary plane 175 extending through body 140 (see Fig. 25a). In the prior art anchor designs this imaginary plane is perpendicular to longitudinal axis 162, thereby evenly aligning all of the external ends of the wing members. In the anchor of the present invention, however, first imaginary plane 175 extends through said body at an angle to transverse cross-section 176 through body 140, wherein cross-section 176 is perpendicular to longitudinal axis 162. As will be understood, angle F of Fig. 25a is preferably substantially equivalent to angle X of Fig. 23, thereby ensuring that at least a portion of the external end of each barb will contact interior surface 102 of the cortical bone adjacent bore 13. Thus, angle F is preferably between about 20° and about 60°, most preferably about 45°. The external ends of the wing members are more preferably tapered as shown so that the entirety of each external end will lie along first imaginary plane 175. Thus, external ends 144, 145 and 146 of corresponding barbs 141, 142, and 148 are aligned along plane 175, thereby adding further support when the anchor is secured within bore 13.

As will be more fully understood later, it is helpful at this point to also define the top of the anchor by a top-line 166 which extends along the surface of body 140 parallel to longitudinal axis 162. First imaginary plane 175 intersects top-line 166 at the point of intersection between the surface of body 140 and imaginary plane 175 which is nearest to proximal end 161. In other words, therefore, the barb extending from body 140 at point nearest to top-line 166 will also have an external end which is closest to proximal end 161. The further from top-line 166 that a barb extends from body 140, the further its external end will be from proximal end 161. The upper portion of body 40 is defined as that half of body 40 nearest to top-line 166, and the lower portion is therefore the remainder.

To provide the alignment described above, the wing members may extend from the anchor body in a number of fashions. Most preferably, however, each barb should be of a similar length in order to provide similar flexing characteristics for each barb thereby ensuring that the anchor will be urged  
5 straight into the bore. Thus, each wing member preferably extends from body 140 along a second imaginary plane extending through body 140 at an angle to cross-section 176. As will be understood, the angle between this second imaginary plane and cross-section 176 should be approximately equivalent to angle F of Fig. 25a. Alternatively, the wing members may extend from the  
10 anchor body at points equidistant from proximal end 161 (i.e., along a plane extending perpendicular to longitudinal axis 162). In order to provide the proper alignment for the external ends of the barbs, however, the length of the barbs in this embodiment would necessarily not all be equivalent to one another.

In order to provide proper support during use, various configurations and numbers of barbs may be employed. Three preferred arrangements are shown  
15 in Fig's 27-29. In the embodiment of Fig. 27, which corresponds to that of Fig's 23-26, five barbs are employed. Thus, barbs 141, 142, and 143 extend upwardly away from the upper portion of body 40, while barbs 148 and 149 extend downwardly away from the lower portion. When the anchor is viewed from the  
20 proximal end towards the distal end (Fig. 27-29), it is seen that barb 141 is substantially aligned with the top-line of body 140. To simplify the description, this will be defined as the 12 o'clock position in terms of a standard clock face. Thus, barb 141 is at about 12 o'clock, barb 142 is between about 10 and 11  
25 o'clock, barb 143 is between about 1 and 2 o'clock, barb 149 is between about 4 and 5 o'clock, and barb 148 is between about 7 and 8 o'clock. It should be pointed out that whenever an odd number of barbs are employed, it is preferable that a greater number of barbs extend from the upper portion of the body rather than the lower portion, since further support is needed in this area.

In the embodiment of Fig. 28, three barbs (152, 153 and 154) are  
30 employed, two of which extend from the upper portion of body 140. Preferably,

barb 153 is between about 10 and 11 o'clock, barb 152 is between about 1 and 2 o'clock, and barb 154 is at about 6 o'clock. In the embodiment of Fig. 29, four barbs (155, 156, 157 and 158) are utilized, two extending upwardly away from the upper portion of body 140, and two extending downwardly away from the lower portion of body 140. Preferably, barb 155 is between about 10 and 11 o'clock, barb 156 is between about 1 and 2 o'clock, barb 157 is between about 4 and 5 o'clock, and barb 158 is between about 7 and 8 o'clock. It should be noted that any of a number of alternative configurations are possible, and the three shown are merely exemplary of the simplest and preferred embodiments.

The anchor of the present invention may be made of any of a number of materials, however titanium or titanium alloys are preferred. The anchor is also preferably singularly molded, however the wing members may be formed separately and attached to body 140 during the assembly process. For example, the wing members or barbs may be attached to body 140 in the manner described in U.S. Patent No's 5,207,679 and 5,217,486. It is preferred, however, that the barbs comprise wire-like members, and may even be formed from titanium or nickel-titanium wires in a known fashion.

As also discussed previously, aperture 150 of anchor 139 is designed so that suture 180 may pass therethrough. In this fashion, two suture tails will extend from aperture 180, and may be used in the manner previously described to elevate the periurethral tissue at the UVJ, for example. It is important during such a procedure, however, that the suture be protected from nicks and other abrasions which would compromise suture strength. While the proximal end of the anchor shown in Fig's 23-30 may be modified to that shown in Fig's 3-4 so that the anchor-insertion tool of Fig's 8-10 can be employed therewith, Applicant has developed yet another anchor-insertion tool which can be employed with the anchor design shown in Fig's 23-30. This new anchor-insertion tool not only protects the suture, it also facilitates proper alignment of the anchor within the bore and also provides a means for tensioning the suture tails in the manner shown in Fig. 20.

An alternative anchor-insertion tool according to the present invention is shown in Fig's 31-35, and comprises a rigid elongate member 250 having:

- anchor-receiving tip 252
- hollow cylindrical intermediate portion 253 having distal end 260 adjacent anchor-receiving tip 252, intermediate portion 253 preferably having a diameter greater than the diameter of tip 252
- handle 251 attached to intermediate portion 253 at the end opposite anchor-receiving tip 252
- passageway 254 providing communication between the interior of intermediate portion 253 and the exterior of the tool

Since anchor-receiving tip 252 is also preferably hollow and its interior is in communication with the interior of intermediate portion 253, an anchor having a suture extending therefrom may be secured on tip 252, and the suture (preferably a pair of suture tails) will extend through tip 252, through at least intermediate portion 253, and through passageway 254. As shown in Fig. 31, passageway 254 is preferably provided in handle 251 and terminates on rear face 255 of handle 251. Since passageway 254 is in communication with the interior of intermediate portion 253, the suture tails may extend along the entire interior length of the tool, and exit at rear face 255 of handle 251. Thus, as shown in Fig. 32, suture tails 260 and 261 extend from anchor 139 held on tip 252, through the entire interior of the tool, and exit at rear face 255. Although the suture tails may exit from the interior of the tool at various other locations, rear face 255 provides a location convenient for the surgeon during laparoscopic urethropexy and similar procedures. In addition, the sutures are completely enclosed within the tool, and thus nicking or fraying cannot occur during the insertion process. It should be noted that the length of suture tails 260 and 261 has been shortened for purposes of clarity.

Anchor-receiving tip 252 should be structured so as to matingly engage the particular anchor being employed. In addition, as described previously, the diameter of tip 252 should be equivalent to that of the anchor body to facilitate anchor insertion. In the embodiment of Fig. 31-32, tip 252 has a slot 256

extending across the diameter of the tip and at least partially along its length, slot 256 capable of matingly receiving tab member 151 of anchor 139. Since it is critical that anchor 139 be properly aligned within the bore in the pubic bone, slot 256 prevents rotation of the anchor during the anchor insertion process. Slot 256 is preferably sized equivalent to or slightly larger than tab member 151 of anchor 139, so that tab member 151 may be placed within slot 256. Tab member 151 may be wedged within slot 256 to hold the anchor on tip 252, or alternatively, end 258 of tip 252 may be secured to proximal end 161 of anchor 139 by means of a releasable adhesive. Any FDA-approved epoxy or other adhesive may be employed, as long as the bond between end 258 and proximal end 161 may be readily broken after the anchor has been seated within the bore merely by pulling the insertion tool away from the bore. In addition, since the suture tails are preferably tensioned between the anchor and handle 251 in a manner to be described, suture tails 260 and 261 will also act to keep tab member 151 held in place in slot 256.

As best shown in the cross-sectional views of Fig's 33-34, the wall thickness of tip 252 should be such that suture 180 which extends through aperture 150 of the anchor tab member will not be compressed by the interior walls of tip 252 when the anchor is in place on tip 252. In other words, the interior diameter of anchor-receiving tip 252 is greater than the sum of the width of tab member 151 plus twice the diameter of suture 180. In this manner, suture 180 will be further spared from damage during the anchor insertion process.

As will be apparent, in order to properly seat anchor 139, anchor-receiving tip 252 should have a length sufficient to ensure that all of the barbs of the anchor are inserted past the cortical bone for proper barb deployment. Since it is preferred that proximal end 161 of anchor 139 be approximately aligned with interior surface 102 of the cortical bone surrounding the bore when the anchor is properly seated within a bore (i.e., external ends of all barbs resting against interior surface of cortical bone), it will be apparent that anchor-receiving tip 252 should have a length approximately equivalent to, or slightly greater than the

thickness of the cortical bone (between about 5 mm and about 8 mm). End 260 of intermediate portion 253 not only acts to drive the anchor into the bore, but also acts as a stop since its diameter is preferably greater than the anchor body and the bore into which it is being inserted. Thus, the proper length for tip 252  
5 will ensure not only that the anchor is driven sufficiently deep within the bore to fully deploy all of the barbs, but also to ensure that the anchor is not driven too far into the bore. In the latter situation, anchor stability may be compromised, and the suture may be damaged by the edges of the bore once the surgical procedure has been completed.

10 In order to facilitate manipulation of the anchor-insertion tool within the laparoscope, a plurality of ridges 259 are preferably provided about the circumference of intermediate portion 253. Ridges 259 are preferably positioned adjacent handle 151, most preferably between about 5 cm and about 10 cm from the handle. Since the diameter of intermediate portion 253 is preferably slightly  
15 smaller than the diameter of the laparoscope to be employed (preferably 7.8 mm and 8.0 mm respectively), ridges 259 will assist in controlling the insertion tool during the procedures of the present invention. Preferably, ridges 259 are sized so as to cooperate with the standard rubber grommet of a laparoscope.

Handle 252 may be secured to intermediate portion 253 by any of a  
20 number of means, however it is preferable that handle 252 be threadably secured to intermediate portion 253. Thus, corresponding male and female threads are provided on the handle and the intermediate portion. Once again handle 251 preferably has curved hand grip surfaces. In this embodiment, however, handle 251 preferably has dissimilar top and bottom portions 271 and  
25 272, respectively. If anchor 139 is secured to tip 252 such that the top-line of the anchor is aligned with top portion 271 of handle 251, the surgeon can readily ensure that the anchor will be properly inserted into the bore. As long as top portion 271 extends directly upwardly during anchor insertion, proper placement will be guaranteed. In order to facilitate alignment, bottom portion 272 of handle  
30 251 is preferably significantly heavier than top portion 271. This weight

differential will further guarantee alignment, since gravity will cause the insertion tool to rotate within the laparoscopic channel to the correct position. It should be appreciated, however, that this alignment means (i.e., and oriented handle) requires that the engagement of handle 251 with intermediate portion 253 be precise. Of course other alignment means may be provided, such as guide lines, leveling bubbles, and the like.

As mentioned previously, providing tension in the suture tails extending from the anchor will not only help in maintaining the anchor on anchor-receiving tip 252, but will also assist during the suture retrieval step shown in Fig. 20 (i.e., when the insertion tool has been partially removed from the laparoscopic channel). Proper tensioning can be achieved by means of at least one notch into which the suture tail(s) may be wedged. Preferably, the notch(es) are positioned adjacent said passageway so that the suture tails may extend through the passageway directly into the notch(es). Thus notches 280 and 281 are preferably provided on rear face 255 of handle 251. In fact, passageway 254 preferably exits handle 251 in an elongated diamond-shaped exit 279, and thus notches 280 and 281 may comprise the opposing narrow corners of exit 279 as shown. When suture tails 260 and 261 leave passageway 254 through exit 279, each tail may be wedged within notches 280 and 281, respectively. In this manner, the tails will be tensioned between notches 280 and 281 and aperture 150 of the anchor. After the anchor has been inserted into the bore, and as the insertion tool is pulled partially out of the laparoscopically channel, suture tails 260 and 261 will slide within their respective notches, thus maintaining the desired tension in the suture tails as needed for the suture retrieval step. To further enhance the tensioning of the sutures, passageway 254 may taper from intermediate portion 253 towards exit 279, thereby providing an additional wedging of the suture tails within the final portions of passageway 254.

It should be noted that intermediate portion 253 preferably has a length of between about 52 cm and about 55 cm to facilitate its use through a laparoscope.

To facilitate a quick and proper anchor insertion process, anchor 139 and the anchor-insertion tool of the present invention may be provided to the surgeon in the loaded form of Fig. 32 (with suture attached and wedged for tensioning as shown). The anchor may even be releasably adhered to the anchor-receiving tip as shown. In this manner, the surgeon can merely open a sterile surgical kit containing preferably two pre-loaded insertion tools (i.e., anchor 139 engaged with anchor-receiving tip and suture tensioned between anchor and notches on handle 251). The pre-loaded insertion tools are sufficiently inexpensive to permit one-time use, or the manufacturer could provide a credit for the return of used anchor-insertion tools which can be sterilized and re-loaded. The surgical kit for performing laparoscopic urethropexy can also include a drill tamper tool, a suture retrieval tool, and/or one or more variously-sized templates (all of which have been described previously). In this fashion, the surgeon will have all of the tools necessary for a quick and simple urethropexy within a small sterile kit.

15 H. Additional Embodiment for Anchor-Insertion Tool

Figures 37-41 depict yet another embodiment for the anchor-insertion tool of the present invention. The anchor inserter of Figs. 37-41 is similar in some respects to that shown in Fig's 8-10. The principle differences are the elimination of an intermediate portion, a lengthening of the grooves, and the positioning of a depression adjacent to the tip. As will be understood shortly, these modifications are significant and provide a considerable advantage over the previously-disclosed design.

The anchor-insertion tool of Fig's 37-41 comprises an elongate shaft 358 having a handle 351 at its proximal end, and an anchor-receiving tip 352 at its distal end. Handle 351 may be provided in any of a variety of shapes, and that shown is merely one possibility. Handle 351 may be secured to shaft 358 by means of threading, glue or other means well-known to those skilled in the art. Additionally, handle 351 may be plastic, wherein the remainder of the insertion tool is preferably stainless steel, or other appropriate material.

Anchor-receiving tip 352 is preferably similar to that shown in Figs. 8-10, which in turn is similar to that shown in Fig's 4-6 of U.S. Patent No. 5,207,679. Thus, anchor-receiving tip 352 is constructed so as to matingly receive anchor 9 of Fig's 3-4. Anchor-receiving tip 352 is cylindrical in nature, having a diameter approximately equivalent to body 40 of anchor 9. In this manner, at least a portion of anchor-receiving tip 352 may pass into the bore in the pubic bone during the anchor insertion process in order to properly seat the anchor completely within the bore.

Anchor-receiving tip 352 has a pair of guide tabs 353 extending from the end of anchor-receiving tip 352 on either side thereof. Guide tabs 353 are sized and shaped so as to be matingly received within the corresponding grooves on anchor 9. Anchor-receiving tip 352 also has a cylindrical slot 354 aligned with the longitudinal access of tip 352. Cylindrical slot 354 should correspond in size and shape to the cylindrical end of anchor 9 in order to matingly receive the same. Guide tabs 353 and slot 354 preferably apply a compressive force against anchor 9 in the manner previously described in order to hold anchor 9 on tip 352.

In order to protect the suture tails extending from anchor 9 during the anchor insertion process, a pair of grooves 355 are provided on either side of the anchor-insertion tool, and extend from tip 352 at least partially along the length of shaft 358 as shown. As compared to the previous insertion tool design, however, grooves 355 extend along a considerable portion of the length of shaft 358. In fact, grooves 355 preferably have a length sufficient to insure that the entire length of each suture tail is positioned within one of the grooves. In other words, when an anchor 9 having a suture extending therefrom is positioned on anchor-receiving tip 352, a suture tail may be placed entirely within each of grooves 355 with the suture terminating prior to end 402 of groove 355 (Fig. 37).

As best shown in Fig 40, grooves 355 also preferably taper in the manner described previously. On tip 352, grooves 355 should be sufficiently deep to ensure that the suture does not extend above the surface of the tip. In other

words, the sutures will be completely hidden within the grooves along anchor-receiving tip 352. A distal depression 359 is provided adjacent tip 352, and grooves 355 preferably begin to taper outwardly just prior to distal depression 359. Although grooves 355 should be at least as deep (as measured from the surface of the shaft 358) as the diameter of the suture, the depth of grooves 355 in the region of depression 359 should be such that a portion of the suture tails will pass through depression 359. In this manner, an O-ring or other retaining band may be secured about depression 359 in order to slidably hold the suture tails within grooves 355. Grooves 355 continue to taper outwardly beyond distal depression 359, and thus, the distance A between grooves 355 will increase. This provides additional strength and rigidity to shaft 358.

The anchor-insertion tool of Fig's 37-41 also has one or more depressions 360 which extend about the circumference of shaft 358 and intersect grooves 355 as shown. Depressions 360 are sized to accommodate a retaining band, such as O-rings 361, in order to slidably hold the suture tails within grooves 355. Thus, depressions 360 should have a depth less than that of grooves 355. Grooves 355 in the region of depressions 360 should also be sized such that the O-rings 361 may compressively and slidably hold the suture tails within grooves 355. Therefore, the difference in depth between grooves 355 and depressions 359 and 360 should be less than the diameter of the suture. A suture positioned within 355 will thus be slidably held between O-rings 361 and grooves 355. In this manner, the anchor insertion method previously described can be readily accomplished with the anchor-insertion tool of Fig's 37-41, wherein tension is applied to the suture tails when the insertion is removed from a bore within which the anchor has been secured.

In the embodiment shown in Fig's 37-41, the retaining bands, or O-rings 361, may be sized such that they act as a grommet during the anchor insertion process. In other words, after anchor 9 has been loaded upon the anchor-insertion tool, the tip of the tool is inserted through a cannula (such as the operative channel of a laparoscope) in order to present anchor 9 to the bore into

which it will secure. Shaft 358 is preferably only slightly smaller in diameter than the interior diameter of the cannula, and O-rings 361 may extend above the surface of shaft 358. O-rings 361 may therefore act as a grommet within the cannula (e.g. the operative channel of a laparoscope), thereby preventing the escape of insufflation gas from the interior of the patient. Furthermore, O-rings 361 provide additional stability because of the tight fit within the operative channel of the laparoscope.

In the presently preferred embodiment, O-rings 361 preferably are sized so that they do not extend substantially above the surface of shaft 358. Although such a configuration lessens or eliminates any sealing effect caused by the O-rings, applicant has found that sealing may also be provided by the interaction of a seal placed on the end of the cannula with shaft 358. Such seals are well-known in the art, and are commonly employed for this purpose. Additionally, since the suture tails are carried entirely within grooves 355, a relatively tight fit between shaft 358 and the cannula may be maintained, thereby further lessening the escape of insufflation gas. Furthermore, end 402 of grooves 355 is located well ahead of handle 351, preferably at a distance sufficient to ensure that during the normal insertion process grooves 355 (and hence the suture tails present therein) will remain entirely within the patient or the cannula. In this fashion, grooves 355 will not permit insufflation gas to escape from the interior of the patient.

Often it is difficult for a surgeon to thread sutures into needles and the like while performing surgical procedures, particularly because of the difficulties caused by surgical gloves. In order to alleviate such problems, applicants have also developed a unique method for threading the sutures onto the anchor-insertion tool. As best shown in Fig. 41, a pair of suture threaders 400 are pre-loaded on the anchor-insertion tool. Similar suture threaders are employed for threading surgical needles and the like. In the present case, each suture threader 400 comprises a length of wire which is bent at its middle to form a loop 401. The opposite ends of the threader are then secured to a pull tab (or handle)

357. In the present case, both suture threaders are preferably connected to a single pull tab 357 as shown. Each suture threader is inserted into one of the grooves 355 as shown, with its loop 401 extending beyond and adjacent tip 352. At its opposite end, each threader preferably extends beyond end 402 of grooves 355 such that pull tab 357 may be readily accessed. O-rings 361 are then secured about the anchor-insertion tool within depressions 359 and 360. This results in each suture threader being slidably held within one of grooves 355 beneath O-rings 361 as shown.

In order to utilize the suture threaders, an anchor is first secured on top tip 352. Since tip 352 will orient the anchor in a pre-determined manner, loops 401 of the threaders as shown in Fig. 41 will align with aperture 43 on anchor 9. In this manner, the surgeon or other medical personnel may simply thread the suture straight through one of loops 401, aperture 43 on anchor 9, and thereafter through the second loop 401. Once threaded, the suture is centered within aperture 43, and then pull tab 357 is grasped. As pull tab 357 is retracted in the direction of handle 351 away from grooves 355, the suture tails will be pulled into grooves 355 by loops 401. As the surgeon continues to retract pull tab 357, the sutures are threaded into grooves 355 beneath O-rings 361, thereby loading the suture onto the device in the proper manner. Thus, the suture threaders provide a convenient way for the surgeon to prepare the anchor-insertion tool for the surgical procedures of the present invention.

As discussed previously, after anchor 9 has been secured within a bore in the pubic bone, the anchor-insertion tool can be retracted away from the anchor by means of handle 351. When the insertion tool is retracted in this way, the suture tails will slide between O-rings 361 and grooves 355 such that the suture tails will extend between the anchor and the tool after this retraction step. The tool should not be completely withdrawn at this point, however, since the suture tails should be permitted to extend between the tool and the anchor in order to allow suture retrieval as shown in Fig. 20. It is also preferred that the suture tails and grooves 355 be sufficiently long so that the insertion tool can be

retracted as shown in Fig. 20 while ensuring that the suture remains beneath all of the O-rings 361. In this manner, the suture tails will be controlled and the barbs of the anchor will be deployed by means of the tensioning of the suture tails. In addition, this insures that the O-rings 361 will remain within the cannula or operative channel of the laparoscope for sealing purposes, if any. Finally, shaft 356 also terminates in distal end 358 which is shown as being tapered. The tapering of distal end 356 provides improved laparoscopic vision during the insertion process. In addition, tapered distal end 356 acts as a stop during the anchor insertion process, thereby insuring that the anchor is inserted to the proper depth.

In the embodiment shown in Fig's 36-38, anchor-receiving tip 352 once again preferably has a length sufficient to insure proper anchor depth. Since anchor-receiving tip 352 preferably has a diameter equivalent to that of anchor 9, which in turn is only slightly smaller than the bore in the pubic bone, distal end 356 acts as a stop during the insertion process. Therefore, the length of anchor-receiving tip 352 should be approximately equal to the depth of the bore minus the length of the anchor. Shaft 358 should be of a length sufficient to permit the tool to be effectively employed through a laparoscope. Thus, shaft 358 has a length of between about 45 and about 60 cm, preferably between about 50 and about 52 cm. The length of the grooves should be sufficient ensure that the entire length of both suture tails can be positioned entirely within one of the grooves, while also ensuring that the grooves remain either within the abdominal cavity or within the operative channel of the laparoscope when the insertion tool is partially retracted as shown in Fig. 20. This ensure that insulflation gas cannot escape through the grooves. Preferably, the grooves between about 25 cm and about 30 cm from the tip. While it is preferred that a at least one depression be positioned adjacent the tip, any number of additional depressions may be provided anywhere along the length of the shaft. Two or three additional depressions 360 are preferred as shown in the accompanying drawings.

The foregoing description of preferred embodiments is by no means exhaustive of the variations of the present invention which are possible, and has thus been presented only for purposes of illustration and description. These modifications and variations will be apparent to those skilled in the art in light of the teachings of the foregoing description, and these modifications and variations are well within the scope of the present invention. For example, the anchor-insertion tools of the present invention may be used with any of a variety of anchor types, provided that the anchor-receiving tip is modified accordingly. For example, the anchor-receiving tip of the tool shown in Fig's 36-38 herein may be modified to correspond with that shown in U.S. Patent No. 5,100,417, thereby permitting the use of the anchor of this patent with the insertion tool of the present invention. Similar modifications to anchor-receiving tip 352 would enable one to use various other types of anchors, and such modifications are well-within the scope of the present invention. Thus, it is intended that the scope of the present invention be defined by the claims appended hereto, and not by the specific embodiments shown in the drawings.

**We claim:**

1. A suture retrieval tool for use in an urethropexy procedure, said retrieval tool comprising:

(a) a retrieving end, said retrieving end comprising a shaft and a sharp tip for penetrating periurethral tissue, said shaft having a longitudinal axis;

5

and

(b) a handle, said handle having a longitudinal axis;

wherein said handle and said retrieving end are configured such that said retrieving end may be inserted into a vagina, through the vaginal mucosa and periurethral tissue adjacent a urethra, and into the space of Retzius, such that  
10 said retrieving end may be employed to snare a suture positioned in the space of Retzius for retrieving said suture into the vagina.

2. The suture retrieval tool of claim 1 further comprising a midshaft positioned between said retrieving end said handle.

3. The suture retrieval tool of claim 2, wherein said midshaft and said shaft of said retrieving end are secured to one another in an angular relationship, and wherein said handle and said midshaft are secured to one another in an angular relationship.

4. The suture retriever tool of claim 3, wherein the angle between said midshaft and said shaft of said retrieving end and the angle between said handle and said midshaft are selected such that when said retrieving end is inserted into the space of Retzius of a patient, said handle will be positioned outside of the  
5 patient's vagina in order to facilitate manipulation of said retrieving end in the space of Retzius.

5. The suture retrieval tool of claim 4, wherein the angle between said handle and said midshaft is between about 120 and about 135 degrees.

6. The suture retrieval tool of claim 5, wherein the angle between said midshaft and said shaft of said retrieving end is between about 135 and about 155 degrees.

7. The suture retrieval tool of claim 4, wherein the diameter of said midshaft is greater than the diameter of said shaft of said retrieving end, such that the end of said midshaft adjacent said shaft of said retrieving end will act as a stop preventing the midshaft from penetrating soft tissue when said retrieving end is inserted through the soft tissue of a patient.

8. The suture retrieval tool of claim 1, wherein said retrieving end has a length sufficient to provide access to the space of Retzius in a patient when said retrieving end is fully inserted into the vagina and through the vaginal mucosa and periurethral fascia adjacent the urethra, but not so long as to permit said sharp tip to penetrate beyond the space of Retzius.

9. The suture retrieval tool of claim 1, wherein said tip has a width less than that of said shaft of said retrieving end.

10. The suture retrieval tool of claim 9, wherein said shaft is round and said tip is substantially flat.

11. The suture retrieval tool of claim 10, wherein said tip has a sharpened distal end and a suture slot located proximally of said distal end, said slot having an entrance thereto, and said slot capable of snaring a suture therein.

12. The suture retrieval tool of claim 11, wherein the entrance to said slot is spaced inwardly from said shaft.

13. The suture retrieval tool of claim 2, wherein said midshaft and said shaft of said retrieving end are secured to one another in an angular relationship, and said handle and said midshaft are secured to one another in an angular

- 5 relationship, said angular relationships selected so as to ensure that the tip can reach a suture within the space of Retzius of a patient when inserted through the periurethral tissue adjacent a urethra, while still allowing a surgeon to manipulate the suture retrieval tool by means of said handle.

14. An anchor-insertion tool for securing an anchor having a suture extending therefrom to a structure within a patient's body, said anchor-insertion tool comprising an elongate shaft having distal and proximal ends, an anchor-receiving tip at said distal end, at least one groove extending from said tip at least partially along the length of said shaft, and at least one depression  
5 extending about the circumference of said shaft and intersecting said groove.

15. The anchor-insertion tool of claim 14, further comprising at least one retaining band positioned in said depression, wherein a suture extending from an anchor positioned on said tip may be slidably held within said groove by said retaining band.

16. The anchor-insertion tool of claim 15, further comprising a handle at the proximal end of said shaft.

17. The anchor-insertion tool of claim 15, further comprising a second groove extending from said tip and at least partially along the length of said shaft, wherein said depression also intersects said second groove.

18. The anchor-insertion tool of claim 17, wherein said grooves extend along opposite side of said shaft.

19. The anchor-insertion tool of claim 17, further comprising a second depression extending about the circumference of said shaft and a second retaining band, wherein said second depression intersects both of said grooves and said second retaining band is positioned within said second depression.

20. The anchor-insertion tool of claim 14, wherein said groove is deeper than said depression.

21. The anchor-insertion tool of claim 19, wherein said retaining bands comprise elastic O-rings.

22. The anchor-insertion tool of claim 19, wherein said second depression is adjacent said tip.

23. The anchor-insertion tool of claim 15, further comprising a suture threader, said threader comprising a wire having distal and proximal ends, and a loop at said distal end, said threader positioned within said groove and beneath said retaining band such that a suture may be inserted into said loop and said  
5 threader may then be pulled away from said groove in order to thread the suture into the groove beneath said retaining band.

24. The anchor-insertion tool of claim 23, wherein said threader further has a handle at said proximal end, wherein said loop is positioned adjacent said tip, and wherein said threader may be pulled away said groove by means of said handle.

25. The anchor-insertion tool of claim 19, further comprising a pair of suture threaders, said threaders each comprising a wire having distal and proximal ends, and each having a loop at their distal ends, one of said threaders positioned within each of said grooves and beneath said retaining bands such  
5 that a suture tail may be inserted into each of said loops and said threaders may then be pulled away from said groove in order to thread the suture tails into said grooves beneath said retaining bands.

26. The anchor-insertion tool of claim 25, wherein said both of said threaders are secured to a handle at their proximal ends, wherein said loops are

positioned adjacent said tip, and wherein said threaders may be pulled away from said grooves by means of said handle.

27. A loaded anchor-insertion tool comprising, in combination:

-an anchor-insertion tool comprising an elongate shaft having distal and proximal ends, an anchor-receiving tip at said distal end, and at least one groove extending from said tip at least partially along the length of said shaft;

-an anchor having a suture extending therefrom; and

-at least one retaining band,

wherein said anchor is positioned on said anchor-receiving tip, said suture extends from said tip along the length of said shaft within said groove, and said retaining band is positioned about said shaft such that said suture is held between said band and said groove.

28. The loaded anchor-insertion tool of claim 27, wherein said suture is slidably held within said groove by said retaining band.

29. The loaded anchor-insertion tool of claim 27, wherein said groove is at least as deep as the diameter of said suture.

30. The loaded anchor-insertion tool of claim 29, wherein said groove is longer than the portion of said suture which extends along the length of said shaft.

31. The loaded anchor-insertion tool of claim 27, further comprising at least one depression extending about the circumference of said shaft and intersecting said groove, wherein said band is positioned within said depression.

32. The loaded anchor-insertion tool of claim 28, further comprising a second groove extending from said tip and at least partially along the length of

said shaft, wherein said suture extends from said tip along the length of said shaft within both of said grooves.

33. The loaded anchor-insertion tool of claim 32, further comprising a pair of depressions extending about the circumference of said shaft and intersecting said grooves, and a second retaining band, wherein one of said retaining bands is positioned within each of said depressions, such that said retaining bands slidably hold said suture within said grooves.

34. The loaded anchor-insertion tool of claim 32, wherein said grooves extend along opposite sides of said shaft.

35. The loaded anchor-insertion tool of claim 33 wherein said grooves are deeper than said depressions.

36. A template for guiding at least one suture through the periurethral fascia and vaginal mucosa adjacent a patient's urethra during a urethropexy procedure, said template comprising:

- (a) first and second wing members extending laterally from opposite sides of the template;
- (b) at least one suture guide aperture positioned in each of said wing members at a predetermined location; and
- (c) a groove extending along the under surface of each of said wing members and intersecting said apertures;

wherein said grooves act to guide the insertion of the tip of a suture retriever into said apertures when said template is positioned within the vagina of a patient.

37. The template of claim 36, wherein the under surface of said wing members adjacent said apertures is beveled in order to assist in manipulation of a suture retriever inserted through said apertures.

38. The template of claim 37, wherein the upper surface of said wing members adjacent said apertures is beveled in order to assist in manipulation of a suture retriever inserted through said apertures.

☒ Further documents are listed in the continuation of box C.

☒ Patent family members are listed in annex.

### \* Special categories of cited documents:

- \*A\* document defining the general state of the art which is not considered to be of particular relevance
- \*E\* earlier document but published on or after the international filing date
- \*L\* document which may throw doubts on priority claim(s) or which is cited to establish the publication date of another citation or other special reason (as specified)
- \*O\* document referring to an oral disclosure, use, exhibition or other means
- \*P\* document published prior to the international filing date but later than the priority date claimed

\*T\* later document published after the international filing date or priority date and not in conflict with the application but cited to understand the principle or theory underlying the invention

- \*X\* document of particular relevance; the claimed invention cannot be considered novel or cannot be considered to involve an inventive step when the document is taken alone
- \*Y\* document of particular relevance; the claimed invention cannot be considered to involve an inventive step when the document is combined with one or more other such documents, such combination being obvious to a person skilled in the art.

\*S\* document member of the same patent family

## C.(Continuation) DOCUMENTS CONSIDERED TO BE RELEVANT

Category *	Citation of document, with indication, where appropriate, of the relevant passages	Relevant to claim No.
A	<p>US 4 911 164 A (ROTH ROBERT A) 27 March 1990</p> <p>-----</p>	36

# INTERNATIONAL SEARCH REPORT

International application No  
PCT/US 97/17232

## Box I Observations where certain claims were found unsearchable (Continuation of Item 1 of first sheet)

This International Search Report has not been established in respect of certain claims under Article 17(2)(a) for the following reasons:

1. ☐ Claims Nos.:  
because they relate to subject matter not required to be searched by this Authority, namely.
2. ☐ Claims Nos.:  
because they relate to parts of the International Application that do not comply with the prescribed requirements to such an extent that no meaningful International Search can be carried out, specifically:
3. ☐ Claims Nos.:  
because they are dependent claims and are not drafted in accordance with the second and third sentences of Rule 6.4(a).

## Box II Observations where unity of invention is lacking (Continuation of item 2 of first sheet)

This International Searching Authority found multiple inventions in this international application, as follows:

see additional sheet

1. ☐ As all required additional search fees were timely paid by the applicant, this International Search Report covers all searchable claims.
2. ☒ As all searchable claims could be searched without effort justifying an additional fee, this Authority did not invite payment of any additional fee.
3. ☐ As only some of the required additional search fees were timely paid by the applicant, this International Search Report covers only those claims for which fees were paid, specifically claims Nos.:
4. ☐ No required additional search fees were timely paid by the applicant. Consequently, this International Search Report is restricted to the invention first mentioned in the claims; it is covered by claims Nos.:

### Remark on Protest

- ☐ The additional search fees were accompanied by the applicant's protest.
- ☐ No protest accompanied the payment of additional search fees.
